

Micro-organisms

- Microorganisms are living structure of micro-scopical size.

- Protista

Prokaryotes

- Bacteria belong to this group

- Bacteria & size of bacteria is measured in unit of a micron

- Study of bacteria

unstained (wet)

- examined mainly for bacterial motility

stained

- Smear made from bacterial culture or specimen

- Heat kills & fixes the bacteria on slide due to coagulation of bacteria protein.

w) Gram's stain :

- Heat fixed smear of specimen is stained with crystal violet for 1 min.

- Gram's stain

Gram positive

- resist decolouration & retain the color of primary stain

Gram negative.

- decolourisation by acetone/ alcohol &
- take stain & appear red.

→ Acid fast stain (Ziehl-Neelsen stain)

- It was discovered by Ehrlich & modified by Ziehl & Neelsen.
- Carbol fuchsin stain is poured on a slide containing fixed smear.

* Morphology of Bacteria:

i) cocci:

- These are oval or spherical cells
- These may be arranged in pairs, chains, clusters.

ii) Bacilli:

- These are rod shaped cells
- coccobacilli: length of bacteria is approx. same as its width.
- streptobacillus: These bacilli are arranged in chains.
- comma shaped: curved appearance
- spirilla: rigid spiral forms.

* Bacterial Anatomy:

- outer layer or cell envelope of bacteria cell consist of 2 components:

a) Rigid cell wall

b) plasma membrane.

i) cell wall:

- It is tough & rigid structure, surrounding bacteria like a shell

ii) Cytoplasmic membrane:

- It is thick elastic semi-permeable layer which lies beneath the cell wall.
- It acts as osmotic barrier
- It acts as a semi-permeable controlling inflow & outflow.

- Ribosomes :- proteins synthesis
 - composed of rRNA
- Mesosomes :- vesicular
 - Multi-laminated
- Nucleus :- DNA is double stranded
 - Bacterial DNA is haploid.
- Flagella :- They are for locomotion
- Fimbriae :- Hair like appendages projecting from the cell surface
 - they are also called pili
